

Tubal Reversal -Celebrate the much awaited stork's visit to your home

As the name implies a tubal reversal restores the blocked or tied fallopian tubes thereby restoring the fertility in a woman. It is a boon for families who wish to have a child even in women having undergone the tubal ligation, to prevent pregnancies. This procedure would be effective if both the partners are fertile.

Success of this procedure depends on the condition of the fallopian tubes. If your tubes are badly damaged during the tubal ligation, it might not be of any use. In many cases, the tubes could shrink extensively where tubal reversal would not be effective.

Is tubal reversal for you?

Typically tubal reversal procedures have high success rates and women report high pregnancy rates. However, in some cases certain adverse conditions like bleeding, and infection could occur. It is a major surgery performed under general or local anesthesia; hence you should be perfectly healthy to undergo this invasive procedure.

The high success rates and the simple procedures are the main attractions of tubal reversal. The duration of this surgical procedure is approximately 1 to 2 hours. If the tubal opening into the uterus is intact the doctor would perform a tubal anastomosis.

However, if there are tube segments extending into the uterus, the doctor might go for a tubal implantation, where the fallopian tube would be inserted into the tube after making an aperture in the uterus. The best part is that tubal reversal involves only 5-10 days of recovery time, which makes it a handy option for working women as well.

Steps in Tubal Ligation procedure Surgery involves general anesthesia. The duration of the surgical procedure is around 1-2 hours. A small incision is made under the navel region for inserting the telescope and another insertion is made under the bikini line. The knots at the fallopian tubes are removed and the ends of the tubes are sutured using very fine sutures. Though it involves a recovery period of 5-10 days, most patients resume daily activities within 1-2 days of the procedure. The Success of a Tubal Ligation Reversal The partners should be sexually healthy and virulent for success. Fallopian tubes comprise only a part of the complex reproductive system which is dependent on various factors like sperm production, ovulation and tube length among others. If a major portion of fallopian tube is cut off during the ligation procedure, the success rates would be low. There should be a minimum of 3 to 4 cm of fallopian tube for pregnancy to occur. Pregnancy can happen soon after the procedure, if all other conditions are favorable. Make sure to hand over a copy of the surgical note of the tubal ligation procedure to the doctor. It might be useful to analyze the overall health of the tube and the success rate well before the procedure. If a portion of your tubes were actually removed, a pathology report is also helpful. You can easily undergo this simple procedure at any of your hospitals in your neighborhood and the tubal reversal cost varies depending on the complexities of cases.
